## DESCRIPTIONS OF NEW SPECIES OF AMERICAN FRESH-WATER CRABS.

BY

Mary J. Rathbun. (With Plates Lxxiil-Lxxvir.)

Family PSEUDOTHELPHUSID Æ.

## PSEUDOTHELPHUSA Saussure.

The synonymy of this American genus with a complete list of spe cies is given by Prof. S. I. Smith in the Transactions of the Connecticut Academy, Vol. II, 1870. In the Amnals and Magazine of Natural History (6) IIr, p. 7, 1S89, Mr. R. I. Pocock describes a new species ( 1 '. temuipes) from Dominica, and gives distinguishing characteristics of all the species. The collection of the United States National Musembe contains no described species of Pseudothelphusa, but the genus is represented by eight new species. They all possess a cervical suture, two epigastric lobes separated by a median suture, two small $Y$-shaperd depressions near the posterior margin of the gastric region, and five rows of spines on the dactyls of the ambulatory legs, three rows above and two below. The exognath of the external maxillipeds is shorter than the ischium of the endognath. The species are grouped according to the character of the front.
$A^{\prime}$. Front not vertically deflexed, but rounding smoothly downward to the inferior * margin.

Pseudothelphusa jouyi.
(Pl. LxXhif Pl. Lxxiv, Figs. 1-3.)
Carapace convex, punctate, smooth, aud shining, much broader in the male than in the female. Cervical suture short and curved, sometimes not continued to the antero-lateral margin. Epigastric lobes faintly indicated by a short horizontal groove in front of them, of a lighter color; sometimes the groove is obsolete, but the color remains. There is no trace of a superior frontal crest, the front rounding smoothly down to the margin, which is not visible from above and is strongly retreating at the center. Median sulcus shallow, dividing the front
into two lobes. Seen from in fromt, the margin is nearly horizontal; seen from below, the two lobes are sliglitly arched forward. There is no onter orbital fissure. The frontal and upper orbital margins are indistinctly ridged, and are granulate in small specimens; in large ones the ridge is meven, the normal gramlation being feebly indicated. Lower orbital margin granulate. Antero-lateral margins finely denticulate, the denticles obsolete in adult males, where the margin is simply uneven. Ischim of maxillipeds elongate, merus subtriangular, endognath but slightly overlapping the jugal area; exognath shorter than the ischinm (Pl. lxxiv, Fig. 3). The interior surface of the body is punctate, the puncte being larger next the orbit. The cervical suture is present on the lower surface. The abdomen of the male (Fig. d) is widest at the distal end of the third and the proximal end of the fourth segment; lateral margins of third and fourth segments ronvex, of fiftl concave. Extremity of appendage of first segment with lateral expansions above, the outer one larger and with a single sharp tooth pointing ontward and downward, the inner oue with a spatulate tooth pointing forward and inward (Fig. 2). The abdomen of the female conceals the stermm. Chelipeds very nequal. Merus with short, stont spines on the inner margin; upper margin with dentiform tubercles on the proximal two-thirds; lower onter margin rounded, with a few gramules; a line of granules on the inner surface near the carpus. Carpus punctate, with a short, broad longitudinal groove above and a stout inner spine. Larger hand in male much inflated, pmetate, smootl; fingers widely gaping, with strong teeth. Smaller hand with margins subparallel, fingers almost meeting when closed. In the females the chelipeds are more nearly equal, and in character resemble the smaller cheliped of the male. Ambulatory legs little compressed; merus slender, with upper and lower margins subparallel, upper margin blunt, with depressed spinules, which become obsolete in adults; carpus feebly spinulous above; propodus, above and below.

Color, a rich reddish brown.
Length of o $27^{\text {min }}$; width, 43.5 ; length of large chcliped, 86 . Length of $₹ 29$; width, 46 ; length of large cheliped, 66.

Many specimens were collerted by Mr. P. L. Jony in 1892 at the following localities in Mexico:

Lake Chapala, abont 5,000 feet clevation, among stomes and shingle on lake shore; Fehuary 19, 7 o, 80 ? , mostly with eggs (17718); Febnary 20,7 大 , : 2 ㄱ, 4 young, all small (17719).

Juanacatlan, Falls of Rio San Jnan, between Lake Chapala and Guadalayara, $\mathrm{A}_{\mathrm{p}}$ mil $26 ; 6$ o , 11 ㄱ, mostly small (17:20).
Prof. A. Dugès has presented specimens from Valle de Santiago, State of Guanajnato; 1 o, 1 ₹ ( 17521 ); also an additional female ( 4122 ) from the same State, probably from the same locality.

This speces bears a strong resemblance to $P$. americana Saussure from Hayti, lut that species is without a cervical suture.

## Pseudothelphusa dugesi．

（l＇l．LXXIV，Figs． 4 antl b．）
This species is so closely related to jonyi that one might easily con－ found the two．It can be distinguisher，however，first，ly the front which is sinmons and slightly bilobed，more abruptly deflexed than in jouyi，with a strong marginal ridge visibie form above and defined by a submarginal groove；viewed from in front the margin is nearly straight；seeomb，by the more compressed meral joints of the ambulia－ tory legs，which are slightly dilated in the middle，the upper edge thin； third，by the appendages of the first segment of the male ahodomen，in which the imner tooth at the extremity is more slender than in jouyi and is directed closer to the appendage．

Color，dark olive brown．
Length of male 21 ；width， 33 ；length of cheliper abont $53^{\mathrm{mm} .}$ ．Length of female， 20 ；wiolth， 33.5 ；length of large cheliped，about 43.
（＇nernavaci，State of Morelos，Mexico，P．L．Jony，August，18：9； 7 大， 1 子（17ヶ2\％）。

A small female from the State of（inanajuato（？），A．Dugès（438！））， has the meral joints of the ambulatory legs proportionally wider than in the specimens from C＇nemavaca，all of which are much larger．

## Pseudothelphusa terrestris：

（Pl．Lxxiv，Figs． 6 and 7．）
This speries mmeh resembles jomyi and rlugesi，but the carapare is wider，the eervieal suture deeper and more conspicmons，the gastric re－ gion more clevated．Front not romding downward as in jouyi but abruptly deflexed as in dugesi，the margin strongly ridged，defined by a well－marked submarginal groove，and visible from above．Viewed from in front the two halves of the margin slope downwarl toward the center．The onter orbital angle is less advanced than in jouyi．The denticles of the antero－lateral margins are less prominent than in speci－ mens of jonyi of equal size，the obliteration in adults being even more complete in this sureies．In the abdomen of the male the terminal seg－ ment is more acute than in jonyi；the appendage of the first segment differs in having at the tip on the onter side a much narrower lateral expansion with a marower，sharper tooth，and on the immer side，a somewhat seythe－shaped tooth．（Ghelipeds similar to those of jougi： the lown outer margin of the merns has a distinct line of grames．The ambulatory legs are more compressed，the merus joints thin abore． and wide in the center．

Color，olive－hrown．
Length of o 21 ；withth， 36 ；length of large cheliped，abont 5 ？$^{\text {mum．}}$ Length of $\circ 19$ ；winth， 32 ；length of large cheliperl，about 33 ．In this female specimen the chelipeds are almost equal．

Collected by Mr．I＇．L．Jony at Atamajar， 3 miles west of（inadalajara， April，15，1892， 3 o ， 2 ㅇ（17723）；also at Parranca Ibara，near（inada－
 above theriver， 3,700 leet above sea level，and 1,500 feet below dinta－ lajia：a，s of，s of，small（177これ）．
> $\Lambda^{\prime \prime}$ ．Front vertically deflexed，forming a blunt arest
> $\mathrm{B}^{\prime}$ ．Crest smooth．

## Psendothelphnsa verticalis．

（11．Lxイバ，Figs． 8 and 9．）
Carapace flattemed，obsemely pumbtate．Cervical suture deep and short，contimed to the margin．Epigastrio lobes depressed．Front vertically deflexed；superion manim not ridged or gramulate，but pre－ senting a smonth，rommed surfare，which is almost stratight and scarrely intermpted by the shallow modian sulens．Inferoftontal margin with a prominent ringer，indistmetly gramulate，a submarginal groove，and a shallow modian sims．The ridge is contimoms with the orbital margin．Antero－lateral margins dentionlate．（brbits deeper than in jomyi，sometimes with a shallow hiatns．In the male abomomen the appentages of the first segment are very difirent from those of the speres above deswibed（Fig．9）．Chalipeds with the merns tri－ amgulate，broadening distally，shorter than in jonyi；npper marein with dentiturm tubereles，whirla beome almost obsolete toward the arpus；
 face with a line of grammes on the onter and distal matrans：ranpore shorter than in jony；large hamd very drep and swollen，math larger than thesmall hand；fingers gringe in the larger cheliped．The ambn－ latory legs are rompressed，hoad；merus joints momel dilated，with a thin upper margin，obsemely dentioulate．

$B^{\prime \prime}$ ．Crest tuberoulate．

## Pseudothelphusa xantusi．

（＇arapace in shape resembling the preeding，slighty eonvox，punc－ tate，gammate anterionly and laterally．＇There is at tare of an addi－ tomal sutme behind the ervical suture，whirh is not an werl rurve， but turns slightly towarl the hori\％ontal near the matgin．Fipisastrio lohes wrld－maked，tuboronlate，separated by a dedp，namow median suldes，which diviles the suprerior frontal crest．This erest is bhat， and is provided with a wide row of tubereles，and near the orlit thens batkwarl，following the lime of the orbit lor athort distance．Jaterior frontal margin with a prominentridse，whirh projects forwarl，is some－ what bilohed，grambate，amd visible from above．Orbits large，mot filled by the eyos；marsin grambate exeept for athort distame be beath the moter angle，where the alssme of grambes simmlates a shallow fissure．Anterolateral mangindentionlate，slightly intermpted
at the cervical suture and between that suture amd the orbital angle. Merus of maxilliped more quadrate, less triangina than in the preceding species. Inferion regions of the anapace very finely grambate and punctate, cervical suture present. Jugal area pubescent as far bark as the stermm. Small cheliped (the only one present) gramulate, punctate, with a broal mems; inner face ontlined below and distally with bead-like tubereles, inner margin with a donble row of blunt spines, increasing in size distally, upper margin with spinulons ruge extending on the outer surface distally. Carpus with a very shallow sulens, a short imer spine; immer marginspinulons. Upper and lower margins of hand subparallel; fingers in contart. The mens joints of the ambulatory legs are hattened, widening toward the renter, denticulate above; capal and propodal joints spiunlous on the upper, inner, and distal margins.

Length, abont 39 ; wilth, 4 ) ; length of smaller cheliperl, abont 61 mm .
? Mexico, John Xantus; a single matilated specimen, of (2゙5ン7).
This sperimen is labeled "Cape St. Lucas", but it is more likely to have come from the vicinity of Manzanillo or Colima, where Mr. Xantus made valuable collections of fresh-water fishes and mollusks in 1862.
$\Lambda^{\prime \prime \prime}$. Front vertically fleflexed, forming an acute lamellate crest.

## Pseudothelphusa colombianus.

(Pl. LxXIV, Fig. 10; Pl. Lxxy, Fig. 1.)
Curapace slightly convex, finely punctate, gramatate anteriorly and near the lateral margins, the grambes more evident in the smaller specimen. Epigastric lobes very prominent, the ridge continned fantly for a short distance in a transverse line of granules. Cervical suture curved, becoming less marked near the lateral margin. Superior frontal margin lamellate, almost straight, tuberculate, divided by a $V$ shaped notel at the extremity of the merlian sulcus. The margin near the orbit turns nearly parallel to the orbital margin and terminates just above the base of the eye. [nferior frontal margin slightly in advance of the superior, simons, with a prominent, horizontal, ridged, and gramlate margin, which is contimons with the tuberenlate or cremulate orbital margin. Front deepest at the onter ends. Antero-lateral margins denticulate, interrupted by a shallow sinus at the cervical suture and another between that aml the orbit. External orbital fissure small and shallow, formed by the absence of one or two granules. Inferior surfare of the carapare finely gramulate near the margin. Jugal region pubescent and anteriorly grambate. Chelipeds of female mequal, punctate. Smaller eheliped much like that of xemtusi, but with few granules; the inner margin has a single row of spines, and below it a row of tubercles. Larger cheliped similar to the smaller, exerpt that the proporlas is muth deeper (Pl. Lxxv, Fig. 1). Fingers in contact when closed. Ambulatory legs little compressed; meral joints widening toward proximal end, denticulate on mper margin, and in the last pair prominently pidged
on lower onter margin; eapal joints spinulous above and distally; propodal joints with small spines abowe, below, and distally.

River David, Chiriqui, United States of Colombia, about latitude sp $^{2}$
 "very rapin streams desemding from Moment Chirigui"; J. A. McNiel, July, 1883; 29 (5012). In the same lootfle there is an ambulatory leg of a specimen one-half again as large, which is apparently the same speries.

## Psendothelphusa lamellifrons.

## (l'l. LxTv, Figs.2-5.)

The canapare of this spereses is allied to that of colombienus; the gramules of the anterior and lateral portions are, however, more prominent, and the cervical suture is smplemented by another shorter parallel suture a little posterior to the first, but not prolonged to the margin. Front similar to that of colombianus, but narower and deeper. External onbital fissure cory shallow and hroad, with a denticle in the middle. Antero-lateral margin very thin and acute, with tine teeth a little more prominent than in colombinums and crowded close together. lsehimm of maxilliped broadening noticeably at the distal end. Abdomen of male contracted at the fifth segment (Fig. 4); the extremity of the appendage of the first segment is laminate, and fodded and compressed laterally, the imer side having two lobes above, the posterior one very large, and the onter side with a blunt tooth pointing forward and outwarl (Fig. 万). Chelipeds in shape and armature resembling those of colombians, lant the grambes are prominent; the upere and lower magins of the basal portion of the larger propodus mone arurate than in those of the female of that species. Fingers in contact. The meral joints of the ambulatory legs are compresserl, very wide at the center, the upper elge thin.

Length, "2"; width, 34.3 ; length of cheliper about 46 m"n.
Isthmus of Tehuanteper, Mexico, F. Li. Sumichrast; : males (3:8!).
Pseudothelphusa richmondi.
(1'l. LXXy, Figs. (i-10.)
Carapace more convex than in the two precerling speries, finely punctate, with saly granales near the lateral margin. Cervical suture deep and almost straight. Ejpigastric lobes well marked. Median sulens short, making a V-shaped noteh in the superior frontal margin. There are thre faint depressed thbercles aranged transversely aross the gastric region, Margins of font and orbits erenulate or gramulate. Superior frontal margin mearly straght, as seen fion above, but seen from in front, the two sides slope downwad to the median line; the onter extremities join the orbital margin. Inferion
margin simous, its lobes visible from above (Fig. (i). The external orbital tooth and the next lateral tooth are finely dentate; posterior to the cervical suture there are ten small spiniform teeth nearly equal in size, followed by a diminishing series of spimes on the postero-lateral margin; the first of the ten teeth has, on one side of the "arapace, one, on the other side two, aceessory spinules. Orbital fissure broad, shallow, U-shaped. Inferior suface of the carapace grammate near the lateral margin, and granulate and pubescent on the jusal area. Maxillipeds broad, considerably overlapping the jugal area; ischinm muth wider at the distal than at the proximal end; merns more quadrate than in preceding species. Last two segments of the male abdomen longer and narrower than in lamellifious (Fig. 7); appendates of tirst segment with superior portion of the extremity armed with three unequal spines, the inferior portion having a concave oval area. Chelipeds unequal, punctate, with scaly gramules, which form rugosities on the outer surface of the merus; merus and "apos armed similarly to those of colombianus, except that there is not a continuous line of granules near the mper margin of the imner surface. Hands rough, with scaly grambes, especially on the margins. Large hand deep, lower margin very convex. Fingers in contact. Meral joints of ambulatory legs compressed and witening toward the center; upper margins of meral, carpal, and propodal joints, and lower margin of propodal joints spinulous; dactyls very slemder.

Length, 32.5 ; width without spines, 49 ; length of cheliped about $70{ }^{\mathrm{mm}}$.
Found on dry land near a small creek which flows into the Escondielo River, 50 miles from Bluefields, Nicaragua, by Mr. Charles W. Riehmond, October 30, 1892; one male (177ゴ).

## POTAMOCARCINUS.

Established by Mihne Edwards* for a species ( $P$. armutus) which differs from Pseudothelphusa in having the superior frontal crest sharp and lamellate, and more prominent than the inferior, the carapace armed with strong spines and an external orbital hiatns.

This genus is doubtfully distinct from Pseulothelphusa, some species of which have an orbital hiatns; in $I$. vichmomd the fiont is sharp and lamellate, though not entirely concealing the inferior crest. In Pseudothelphuse can be seen every gradation between the sharp-crested front and the smooth front withont a ridge. There seems to be no external character to distinguish Totamocarcinus except the strong marginal teeth, which is hardly a generic character. The following species is therefore placed provisionally in this genns.

[^0]
## Potamocarcinus nicaraguensis.

 X. 1 . 100, 18.58.

Stimpson, in his mpmbished report on the Gpastarea eonlereded hy the North Pacitic Exploring Experlition, says af $I^{\prime}$. armatus, "We have but ond specimen of this speries, a smatl male, half an inch in length. It difiess somewhat fiom the lage female desmibed by Mibue Edwards, in that the rarapace is pmotated, mod, toward the lateral margims, somewhat grambated. The seromd amd third antero-lateral tecth are bitid. Datyti searerly quadramgular', ahost romblerl, also smaller amd less spimbose. It was fomm at (Omotepee lstand in Lake Nicarasua, by Mr. ('harles Wrieht, botanist of the experlition."
 agree with Stimpson's diatuosis, exrept that the dactyls are not less spinmons than in Mihe Edwards's ligure of armutus.
('arapae lonoter antrionly than in armatus, slightly convex, distinctly maked with small pmotar, gramate near the lateral margins, the grambes most prominent in fomos specimens. Cervical sulens derp and corved; there are wide and deep growes rither side of the postrion gastrid area, and small Y -shaperl growos between them. The epigastrie lobes are well manked, divided by a namow sulens leading to the front. Smperior frontal margin horizontal, gramatate, more advanced in the rentral portion; median fissure V-shaped. Front
 scparately ardaed upward. Postombital tooth obtuse, outer marain rombled. Secoml tooth broader, obtuse, atten with ome or more areses sory tedth on its margins. Thire tooth, that dimectly posterion to the cervieal shtme, hroad, very ramiable in shape, but alwas bilobed. Rematning large terth, fom to six in momber, irregular in shape and position, achere spinoms. There are oftern small intervening tectlo. Postero-lateral margin with serama spmales which decrease in size from the lateral angle. Wxtermal onbital hiatus deep and widr: orbital manerin grambate. Lawer surfare of the carapare grambate near the lateral margin amd on the jusal area. The margin ot the epistome is
 the endognath of the extemal maxillipeds is very wiole and rovers a portion of the fugal region; the exognath is moth shorter than in "'mutn, meve exceding one-half the length of the ischimm. 'The appendages of the first segment of the mate abdomen are very stont, and at the smmmit present a eomeave outer sumfere which hats a spine at the antero-inferior angle, a lobe at the anterosmperior and postero-

Fig. 3). Andomen of female very lanere, concealing the sternm. (heli peds long and strong, mernal, punctate; merus roughened above, inner margin spinoms, the spines longer and stronger at the distal end; inferior margin granulate. Carpus with a very shallow median groove near the center, and a stont spine on the inner margin. Large hame much swollen, deep; there is a short line of tubercles on the inner side of the lumer margin near the carpus; dactyl strongly arehed; fingers and lower surface of hand speekled with small dark spots, which, on the fingers, are grambous; teeth of prehensile edges irregular, broad, and strong. Smaller hand less broad and deep; tingers in contact or slightly gaping; otherwise as in the larger hand. The chelipeds of the female are shorter and more slender than those of the male. 'The merns joints of the ambulatory legs are slightly compressed; upper and lower margins almost parallel; upper margin obseurely granulate; carpal joints marmed; propodal joints spimulons on the distal portion; dactyli compressen, with five rows ut spines.

Length of $\delta 55^{\text {mun }}$; wilth withont spines, 8 ; ; approximate length of larger cheliped, 1.58; length of propodns, 90 ; depth, 37 ; thickness, 23 . Length of 9,03 ; wilth, without spines, 85 ; approximate length of larger cheliperd, 1:35; length of propodus, 71 ; depth, 2.); thickness, 1 in.
 from two inches to three-fouths of an inch in length.

Near Greytown, Nicaragua, Dr. Louis F. II. Birt; $2 \overbrace{}^{\circ}, 3$ of (1378s) all large. Greytown is at the month of the river San Jnan, an outlet of Lake Nicaragna.
Rio Frio, Costa Rica, a tributary of the Sam Jnam, Charles W. Richmond, Marel 3,1892 ; one of (17957).

## EPILOBOCERA Stimpson.

In 1sif0 Stimpson institnted the genus Epilobocera (Ann. Lye. Nat. Hist. N. Y., vir, p. 234) for a fresh-water crab of the family Thelphesidie, distingmished by the frontal process mecting the internal suborbital lobe, behind which the antema passes to the orbital cavity. The merns of the external maxilliped is transverse, its anterior margin rombled, and the palpus goniarthoid. The type species, E. cubensis, was found in fresh-water streams near Santiago, Cuba.
In 1870 Prof. S. I. Smith (Trans. Comn. Acad. If, p. 150) gives a more detailed description of E. cubensis, and describes another species, b. armata, probably from the Bahamas. The generic diagnosis should be amended so ass to include species in which the frontal process nearly joins the suborbital-lobe, the character being at best of donbtinl value. The fullowing distinguishing characters may be added: A process projects from the upper side of the expiratory canal, and the exognath of the extermal maxillipeds overrearches the ischimm of the endognath.

## Epilobocera haytensis.

(1'l. sxxinl, Figs. 1 and 5.)
Canapace very slightly convex, fincly grambate, and pumetate. Cervical sulcus deep. ('ardiae region with shallow depressions on either side, and two mime Y-shaped wroves in the sulens between the gastrie and eardiac regions. Epigastric lobes distinct, separateri by a well-marked sulens, whiclo extends forwad and forms a wide median sims in the superior frontal margin. This margin is prominent and nearly straight when seen fiom above, lont slopes downward toward the middle, and in the larger specimen the two halves are inclined slightly backward toward the median line. The mangin is mevenly tuberenlate. and near the orbital horder it is dirested backward and ends above the base of the eye. The inferior margin of the front is thre-lobet, the median lobe directed downward and fow warl, the lateral lobes rommed and horizontal, projecting well beyond the superior margin. The margin is crombate, and also the orhital borler. which is contimons with it. There is a broad hiatus beneath the onter angle of the orbit. The internal suborbital lobe is very broad and concare, and nearly, but not quite, tonches the subfontal process. The antero-lateral margin is marked by small hont teeth, irregnlat in size amd shape, and interrupted hy a wirle sinus at the ervieal suture, and another near the extermal orbital angle. The teeth become smaller and more indistinct near the postero-lateral margin, which is slightly concave, smooth, and romaded The marginal teeth are less plamly marked in the smaller specimen. Labial border of the epistome with thre lobes; median lobe acute, projecting downward and slightly forwad ; lateral lobes shorter, less aroute, their immer margins arehed mpward and forwath. The margins of the lobes are thberculate. On the lower side of the carapace there is a line of tubreles following the reveral suture and the anterion jortion of the jusal area is tuberoulate. The embognaths of the extermal maxillipeds in width do mot excerd the bureal eavity; the merns is more or less quadrate, the antero-external angle romedel (rig. 5 ). The male abomen is widest at the third segment, and does mot taper regularly to the last. but the mareins of the formoth, fifth, and sixth segments are separately comvex. The appendages of the first semment are bent ontwards at almost al digh angle inear the extremities, whell are lobed amol spmulifexms. C'helipuds momul. The mems is amed with stont
blunt spines on the inner marsin, irregularly dentate on the uper margin, scabrous on the upper portion of the onter surface, and with a line of small tubereles on the lower onter margin; carpus faintly seabous near the merus, with astrong, blunt spine at the inner angle. Hand inflated; fingers irregularly dentate within, gaping to the tips in the male, in contact in the female. Ambulatory legs flattened, sparingly pubescent; merus joints denticulate above; carpal joints indistinctly denticulate above, with a few spinules on the distal margin; propordal joints with two rows of spines above and below, the lower ones the longer, and one row on the distal margin; dactyls with three rows above and two below, with fewer spines in the lower rows.

Length of larger specimen, a female, $46^{\mathrm{mm}}$; width, 76 . Length of o 21.5 ; width, 35 .

Hayti; A. G. Younglese; ㅇ (3ə16). San Domingo; W. M. Gabb, 187s; ot (3192).

## Epilobocera granulata.

(Pl, LxXVif, Fig. 6.)
The specimens are smaller than in the preceding species, and are sexually immature. The species is closely allied to haytensis. The areolations of the carapace are the same. The anterior portion is more distinctly gramulons, especially the epigastric lobes, and the branchial regions are coarsely gramulate near the margins. The antero-lateral margin is not intermpted at the cervical suture, but there is a deep sims next the postorbital tooth, and the first tooth following is very small. The next 6 to 9 teeth are larger and more regular than the remainder. Snperior frontal border as in haytensis. The inferior frontal borler is thin, more advanced than the superior, and in a front view the two halves are seen to arch upward. The extemal suborbital fissure is very shallow, scarcely more than an interruption of the denticles of the orbital border. The subhepatic and subbranchial regions are granulate, and the cervical ridge is present as in haytensis, but the jugal area is smooth, except at the anterior extremity. The epistome has three acnte lobes, tuberculate on the margins, similar to those of haytensis. The maxilliperls in width exceed the buccal cavity; the merus has the antero-extemal angle much more arcuate than in haytensis (Fig. 6). Abrlomen of male narrower than in haytensis, especially noticeable in the pennltimate segment. The merus and carpus of the chelipeds of the male are similar to those in haytensis; the carpal spine is sharper. Hands little dilated; fingers very slightly gaping at their base. Ambulatory legs sparingly pubescent, with meral joints denticulate above; carpal, propodal, and terminal joints armed as in haytensis.

Length, 13.5; wilth, 23 millimeters.
West Indies (6705). Four specimens, all more or less mutilated. Two of them are males, and probably also the other two,

## Framily TRICIIODAC'TVLAD.E.

## Trichodactylus quinquedentatus.

 Sufare smootlo, shining, punctate, the punctir iregular in size and mmeroms. There is an f-shaped depression in the renter of the earapare. Front namower than in pumfatns, donsisting of two hroad lobes more pronouncol than in sperimens of penctatas of equal siza. Exter
 tive teeth, besides the orbitah, the tirst there shatp and spiniform, the last two hhant. Canapare widest at the lomelh touth. Frontal, ombital amd lateral matgins ridged aml smonth. (Onter matrin of merns of maxilliped ridged amd mote strongly prodnced at its antorion athgla than in punctatus. Alolomen of femate covering the stemmen tomi hal segment broarly triangular, fommed at the tip. Cheliperls in femate mergat, pumetate; merns triangular, mper matein atote, with a tooblh at the distal emd: loweremble with a small shat spine on the onter amd the imer margin, amb a bhat poperefon at the extemity ol the onter mangin; entus with a spinc om the immer mangin. Hamds convex beneath, almost stmight above: smaller hamd abont two thimes
 very slender; meral joints not dilated. Ambmbatory loges, fingers, and
 ри!

Length, I! ; width, å millimaters.
Fomml in a ditrh, almost dry, nean the Resomdide liver, so miles
 one lemale (17526)
 ummber at lateral tecth.
